

Take-Home-Assignment

Plan on roughly three to four hours.

The idea

A small internal service for managing web extraction jobs. An operator can register an extraction job, see the jobs they have registered, and start or stop one. Each job draws against a monthly page allowance for the account.

The details are yours. Make reasonable calls and note the assumptions you make.

Build it

A minimal, rough version with a simple web UI for the core actions: register a job, see the list, start or stop one. Any stack you like; in-memory storage is fine. Keep it small and unstyled.

Test it

Decide what testing this service needs, and add it.

Send back

- The project as a zip (exclude dependencies), with one line on how to run it and the tests.
- A short `STRATEGY.md` in your own words.
- A three-minute screen recording with your voice and the project open, unscripted, covering: your testing approach and one decision behind it; where the build is riskiest; and how you used your AI agent, including a place it got something wrong and what you did about it.

Using an AI agent is fine. Decisions you cannot explain are not.
